

SOLUTION REQUIREMENTS

Auto Ticket Classification Using Flow Designer

Date	30 September 2026	Team ID	MKU201AutoTicket
Project Name	Auto ticket classification using Flow Designer	Maximum Marks	4 Marks

Project overview: The project uses ServiceNow Flow Designer to automatically classify incident workflow records based on ticket information such as short description/category and then update the record through configured flow actions. The implementation shown in the provided evidence includes a custom Incident Workflow table and a flow named Auto Classify School IT Tickets Final.

Step 1: Functional Requirements (FR)

S.No	Requirement Category	Requirement Description	Priority
1	Authentication	Users access the ServiceNow application through the instance's configured authentication. Only authenticated users can create or work with ticket records according to their assigned access.	High
2	Authorization levels	Access to incident workflow data and flow configuration is controlled through ServiceNow roles and permissions. Administrative/developer access is separated from normal ticket-user access.	High
3	External interfaces	The solution operates inside ServiceNow and uses Flow Designer actions and the Incident Workflow table. No external API or third-party database is shown in the supplied implementation evidence.	Medium
4	Transactions processing	When an Incident Workflow record is created, the active flow evaluates the ticket information and performs configured Update Record actions to classify/update the record.	High
5	Reporting	The resulting Incident Workflow records can be viewed through the ServiceNow table/list interface. The supplied implementation does not show a separate custom reporting dashboard or export.	Medium
6	Business rules, etc.	Classification logic is implemented with Flow Designer conditions. The shown flow contains branches for WiFi Network, Project or Hardware, and Forgot password scenarios, followed by configured record-update actions.	High
7	Compliance to laws or regulations	The solution should follow the organization's ServiceNow access-control, data-handling and privacy requirements. No specific legal or regulatory standard is identified in the supplied project evidence.	Medium
8	Other	The custom Incident Workflow record contains fields including Caller, Category, Sub category, Short Description, Description, State, Assigned Group and Assigned to, supporting classification and routing information.	High

Step 2: Non-Functional Requirements (NFR)

The following acceptance criteria are project targets for the implemented workflow; they are not presented as measured production results.

S.No	NFR Category	Requirement Description	Target Metric / Acceptance Criteria
1	Performance & Speed	The classification flow should process a newly created ticket without unnecessary manual steps and update the record promptly after the trigger runs.	Target: classification/update should normally complete within 5 seconds of flow execution under normal instance load.
2	Scalability	The design should support increasing numbers of Incident Workflow records by using Flow Designer automation rather than manual classification for each ticket.	Target: workflow remains usable as ticket volume grows, subject to ServiceNow instance limits and flow execution capacity.
3	Security & Data Privacy	Ticket information should be accessible only to authorized ServiceNow users/roles. Sensitive ticket data should remain within the configured ServiceNow environment.	Acceptance: unauthorized users cannot access protected records; permissions follow the configured ServiceNow access model.
4	Reliability & Availability	The classification process should execute consistently when its trigger conditions are met and should not depend on manual intervention for normal cases.	Acceptance: each eligible record starts the configured flow; failed executions are visible through ServiceNow flow/action status.
5	Usability & Accessibility	The ticket form should present the classification-related fields clearly, including Caller, Category, Sub category, Short Description, Description, State, Assigned Group and Assigned to.	Acceptance: users can create/update records using the configured form fields without needing to edit workflow logic.
6	Other – Maintainability	Classification rules should remain editable in Flow Designer so new ticket patterns or routing rules can be added without redesigning the whole application.	Acceptance: a developer/admin can modify conditions and Update Record actions in the flow and republish the updated flow.

Implementation Evidence Reflected in the Provided Screenshots

- A custom table labelled Incident Workflow is configured with fields such as Caller, Category, Sub category, Short Description, Description, State, Assigned Group and Assigned to.
- The Flow Designer flow is named Auto Classify School IT Tickets Final and is shown as Active/Published.
- The flow trigger is based on creation of an Incident Workflow record.
- The shown decision branches include SD is Wifi Network, SD is Project or Hardware, and SD is Forgot password.
- Update Record actions are used to modify the Incident Workflow record after a classification branch is selected.
- A ServiceNow Update Set named Project Update Set is shown for capturing project changes, and an exported XML file is shown as part of the update-set workflow.

Project Summary & Acceptance Checklist

Project: Auto ticket classification using Flow designer

Date: 30.09.2026

Team ID: MKU201AutoTicket

Item	Expected Project Outcome	Status
Custom table	Incident Workflow table is available with the required ticket/classification fields.	Implemented
Trigger	A newly created Incident Workflow record starts the classification flow.	Implemented
Classification logic	Flow Designer evaluates configured short-description conditions.	Implemented
Record update	Update Record actions modify the workflow record after classification.	Implemented
Maintainability	Rules can be updated through Flow Designer and captured in an Update Set.	Implemented
Testing	Flow can be tested from Workflow Studio using the Test option.	Available

Notes

1. This document follows the supplied three-page Solution Requirements template and fills its Functional Requirements and Non-Functional Requirements sections for the stated project.
2. Statements about the implementation are based on the ServiceNow screenshots supplied with the request. Where the screenshots do not establish a specific external integration, regulatory standard, or measured performance result, the document explicitly identifies the item as a project target or as not shown.
3. The performance, scalability, reliability and usability metrics are acceptance targets for the project, not claims that those measurements have already been achieved.
